HW 6: Due 10/03

*"If you fish can catch nothing, you have
still caught a lesson."
—Matshona Dhliwayo*

Problem 1. (10pt) You are standing at the corner of 6th and 40th while your friend is standing at the corner of 2nd and 59th.

- How many blocks are you from your friend?
- How many blocks are you from your friend 'as the crow flies'?
- What is your Euclidean distance between you and your friend?
- What is your Manhattan distance between you and your friend?

Solution. We can draw a picture of this to aid in the solutions:

- Whether we go 6 blocks East and then 19 blocks North, 19 blocks North then 6 blocks East or any combination 'in-between', you must travel $4 + 19 = 23$ total blocks; that is, you must travel $(6 - 2) + (59 - 40) = 4 + 19 = 23$ blocks
- This is the 'straight line distance (the dotted line above). This is the length of the hypotenuse of a right angled triangle with legs 4 and 19. But then the distance is $\sqrt{4^2 + 19^2} = \sqrt{16 + 361} = \sqrt{377} \approx 19.4165$ blocks.
- This is the straight line distance that we computed in (b). Being more formal, we have...

$$d = \sqrt{(6 - 2)^2 + (59 - 40)^2} = \sqrt{4^2 + 19^2} = \sqrt{16 + 361} = \sqrt{377} \approx 19.4165 \text{ blocks}$$

- This is the 'block' distance we computed in (a). Being more formal, we have...

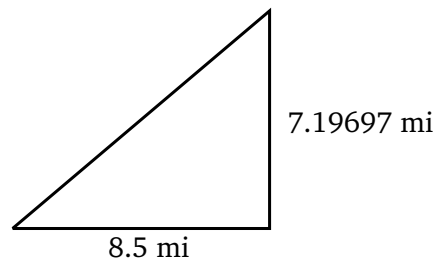

$$|6 - 2| + |59 - 40| = |4| + |19| = 4 + 19 = 23 \text{ blocks}$$

Problem 2. (10pt) You see a plane at cruising altitude (approximately 38,000 ft) flying over a nearby airport. You know that the airport is 8.5 mi away. How far is the plane from you at this moment? [5,280 ft = 1 mi]

Solution. First, we compute the cruising altitude to miles:

$$\frac{38000 \text{ ft}}{5280 \text{ ft}} \left| \frac{1 \text{ mi}}{5280 \text{ ft}} \right| = 7.19697 \text{ mi}$$

Drawing a picture, we can see the distance is the hypotenuse of a right angled triangle. We can then use the Pythagorean Theorem.

$$\sqrt{(8.5 \text{ mi})^2 + (7.19697 \text{ mi})^2} = \sqrt{72.25 \text{ mi}^2 + 51.7964 \text{ mi}^2} = \sqrt{124.046 \text{ mi}^2} \approx 11.1376 \text{ mi}$$

Problem 3. (10pt) Suppose you are designing a custom fish tank. The fish tank will be a rectangular box will be 36 in x 18 in x 19 in. The top will be open so that the tank can be accessed.

- If you have to cover the exposed sides with a special plastic coating, what is the area of plastic coating that is needed per tank?
- How much water, in gallons, can the tank hold? [$1 \text{ ft}^3 = 7.48052 \text{ gallons}$]
- Suppose you are going to put a volcano in the tank, which will have the shape of a right circular cone. If you put the largest possible volcano in the tank, how much water will it then take to fill the tank?

Solution.

- This is a rectangular prism. However, because the top is open, it does not contribute to the area because there is no surface there. Moreover, because the bottom of the tank sits on a table, it also does not need to be covered. Therefore, the exposed area (surface area) is...

$$2lh + 2wh + 0lw = 2(36 \text{ in})(19 \text{ in}) + 2(18 \text{ in})(19 \text{ in}) = 1368 \text{ in}^2 + 684 \text{ in}^2 = 2052 \text{ in}^2$$

- This is the volume of the tank. This is $V = lwh = (36 \text{ in})(18 \text{ in})(19 \text{ in}) = 12312 \text{ in}^3$. We now need to convert this to gallons:

$$\frac{12312 \text{ in}^3}{12 \text{ in} \times 12 \text{ in} \times 12 \text{ in}} \times \frac{7.48052 \text{ gallons}}{1 \text{ ft}^3} = 53.2987 \text{ gallons}$$

- Because the base of the volcano has to fit in the width or length of the tank, it can have a diameter of at most 18 in (the smaller of 36 in and 18 in). This is the diameter of the circular base. Therefore, it has a radius of $18/2 = 9 \text{ in}$. The largest height of the tank is 19 in. Therefore, the volume of the largest possible volcano is $V = \frac{\pi}{3} r^2 h = \frac{\pi}{3} \cdot (9 \text{ in})^2 \cdot 19 \text{ in} \approx 1611.64 \text{ in}^3$. Because the volcano will take up this volume, the remaining volume of the tank can be filled with water. This volume is $12312 \text{ in}^3 - 1611.64 \text{ in}^3 = 10700.4 \text{ in}^3$. In gallons, this is...

$$\frac{10700.4 \text{ in}^3}{12 \text{ in} \times 12 \text{ in} \times 12 \text{ in}} \times \frac{7.48052 \text{ gallons}}{1 \text{ ft}^3} = 46.3221 \text{ gallons}$$

Problem 4. (10pt) Suppose a courtyard at some hedge fund is approximately elliptical in shape. It is approximately 50 ft ‘the long way’ and 35 ft ‘the short way.’

- (a) What is the area of the courtyard?
- (b) If someone can push mow approximately 320 square foot of lawn per minute, how long does it take to mow the courtyard?
- (c) If every 1,000 square foot has to be fertilized with 10 lbs of fertilizer and the fertilizer costs \$2.08 per pound, how much does it cost to fertilize the courtyard?

Solution.

- (a) Because the area is elliptical, we know that $A = \pi ab$, where a, b are the length of the semimajor/semiminor axis, respectively. Because the courtyard is 50 ft ‘the long way’, the semimajor axis is $50 \text{ ft}/2 = 25 \text{ ft}$. Because the courtyard is 35 ft ‘the short way’, the semiminor axis is $35 \text{ ft}/2 = 17.5 \text{ ft}$. Therefore, the area of the courtyard is $A = \pi ab = \pi(25 \text{ ft})(17.5 \text{ ft}) = 437.5\pi \text{ ft}^2 \approx 1374.4468 \text{ ft}^2$.
- (b) We know net change, C , is related to a constant rate, r , and time, t , via $C = rt$. We know that the net change of mowed lawn we want is approximately 1374.4468 ft^2 . The rate at which the lawn can be mowed is $320 \text{ ft}^2/\text{min}$. But then we have...

$$C = rt$$

$$1374.4468 \text{ ft}^2 = (320 \text{ ft}^2/\text{min})t$$

$$t \approx 4.295 \text{ min}$$

- (c) We know that the courtyard is approximately 1374.4468 ft^2 . Each 1,000 square foot must contain 10 lbs of fertilizer. But then the amount of pounds of fertilizer required per square foot is $10 \text{ lb}/1000 \text{ ft}^2 = 0.01 \text{ lb}/\text{ft}^2$. Using $C = rt$, we know that the courtyard requires approximately $1374.4468 \text{ ft}^2 \cdot 0.01 \text{ lb}/\text{ft}^2 = 13.744468 \text{ lb}$ of fertilizer. Each pound of fertilizer costs \$2.08. Therefore, again using $C = rt$, the total cost of 13.744468 lb of fertilizer is $13.744468 \text{ lb} \cdot \$2.08/\text{lb} \approx \$28.59$.
